The work presented here is the result of a collaboration with Ph.D candidate Sidi Wu and professor Jiguo Cao from Simon Fraser University and with research intern Valentin Larchevêque from Université Montpellier.

Functional data Functional Output layer Functional Input layer Deep learning models and implementation

The talk

- Definition of functional data.
- Parametric representation of functional data.
- Regression of functional data.
- Functional layers.
- Proposed models.

L Introduction

A brief introduction to functional data

- ▶ In functional data analysis (FDA), a replication $x_i(t)$ $t \in T$ is a function.
- The space over which the function is defined T can be time, spatial space, or higher-dimension spaces.
- A data set is a collection of such functions
 S = {x_i(t) | i ∈ (1,...,n)} over the same space.
- The data is collected as a collection of points over the space.

L Introduction

A simple functional data set.

- For the presentation, we suppose T is one-dimensional and is some measure of time.
- From now on, let us say the space-time is [0, T].

Introduction

A sample of points over T

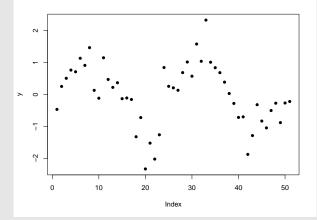

Figure: Samples from a functional data.

L Introduction

A simple functional data set.

This is different from time series:

- We are not trying to forecast the functional data.
- We must have multiple repetitions over T.

Introduction

Multiple subjects: A sample of points over T

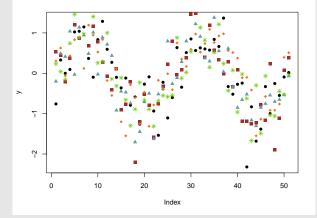

Figure: Samples from multiple functional data.

Parametric representation

- It is assumed that the functional data is a realization of an underlying smooth stochastic process.
- It is common to interpolate points and produce a smooth representation for x_i(t)
- This smooth representation is later used in the analysis.

Parametric representation

- The standard approach to do so is to use some basis expansion; a set of basis functions (that cover the space [0, T]) and a set of basis coefficients.
- Thus, the continuous and smooth curve is estimated as a linear combination of those functions and parameters.

$$\triangleright x(t) = \sum_{k=1}^{K} c_k B_k(t)$$

Parametric representation

$$\triangleright x(t) = \sum_{k=1}^{K} c_k B_k(t)$$

- We obtain a continuous representation of x(t) (can be evaluated for any t ∈ [0, T]).
- We only need to *learn* a discrete number of parameters to produce a smooth and continuous representation of functional data.

$$\sum_{j} [x(t_j) - \sum_{k=1}^{K} c_k B_k(t_j)]^2$$

Figure: Keep the curve (smooth and continuous representation)

ロトスロトスロトスロト ヨーのへの

Parametric representation

- The data is now represented using the B-Spline basis functions (for instance with order 4 and 9 interior knots)
- This observation is later used in the analysis.
- With the following coefficients: [-0.65115973, 0.53578405, 0.70073762, 0.94566931, -0.59899313, -0.89844612, -0.54772926, 0.79263628, 1.21055785, -1.36245376, -1.40150503, 0.05021092, -0.04074864]

Parametric representation

Functional data representation

Smoothing has multiple benefits:

- Dimension reduction
- Easy-to-compute derivatives
- Manages irregularly-spaced data
- Smooth out measurement errors

Parametric representation

Irregularly-space data

What is irregularly-spaced data:

- Irregularly-collected data.
- ▶ Different subject/repetitions i are collected at different times t ∈ [0, T]
- The can also be collected a different number of times.

Parametric representation

Irregularly-space data

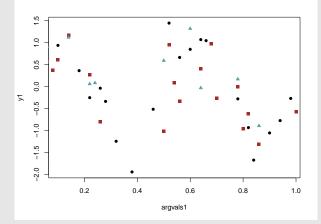

Figure: Irregularly-space functional data.

Goals and problems of functional data analysis

Problems in functional data analysis

- 1. Represent the data in a way that aid further analysis.
- 2. Display the data so as to highlight various characteristics.
- 3. Study important sources of variation among the data. (Functional principal component analysis)
- 4. The regressions of functional data onto scalar variable and vice versa.

Goals and problems of functional data analysis

Functional Regression

- We cannot simply treat the observed points over [0, T] as scalar and use regular regression.
- Different observations might observe data at different moments.
- Different observations might be observed a different number of times.
- Observations at time points close to another are related.

Goals and problems of functional data analysis

Traditional Regression cannot be directly applied.

-Functional data

Goals and problems of functional data analysis

Functional regression problems

- Function on scalar (FoS) regression.
- Scalar on functional (SoF) regression.
- Function on function (Fof) regression.

-Functional data

Goals and problems of functional data analysis

Function on scalar regression (FoS)

- Scalar predictors, functional response.
- A common approach is to smooth the response, $y_i(t) = \sum_{k=1}^{K} c_k^i B_k(t)$
- The we regress the coefficients c_k onto the predictors x.
- Thus we learn a matrix of parameters B such that c = xB using least square.
- This means, doing two steps of least square sequentially.

Goals and problems of functional data analysis

Scalar on function regression (SoF)

- Functional predictors, scalar response.
- We take the inner product between the functional predictor and a functional weight.
- The model takes the form: $y = \beta_0 + \int_T x(t)\beta(t)dt + \varepsilon$
- A bit more complicated than FoS regression.

Goals and problems of functional data analysis

Scalar on function regression (SoF)

A simple solution is to express the parameter β(t) using a basis expansion: β(t) = ∑_k c_kB_K(t)

$$Y = \beta_0 + \sum_k c_k \int_T x(t) B_K(t) dt + \varepsilon$$

The parameters are now the basis coefficients (c_k) and they can be estimated provided a numerical solution for ∫_T x(t)B_k(t) for all k.

Functional data

Goals and problems of functional data analysis

Functional regression

- Those are not the only way to proceed.
- Our proposed method is inspired by these.

Neural network architectures for functional data analysis

Integrating deep learning into functional data analysis

- We seek a solution to solve all three regression problems described.
- We seek ways that functional data can be integrated, either as input or output, in deep learning models.
- We focus on designing input and output layers that can be connected to already existing deep learning architecture (CNN, LSTM, RNN, etc...)
- Using the functional data as it is collected,
- but considering the smooth and continuous assumption.

Functional Output Layer

Functional Output Layer

- We want to design a functional output layer for neural networks (NN).
- To integrate our model into currently existing deep learning architecture, we have to make sure it can be trained using back-propagation.
- The predictors entering the model can be of any form.
- We propose to first output k basis coefficients, and then through a deterministic layer we reconstruct the functional response.

-Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

- The functional data that we have is the following:
- We know tⁱ = [tⁱ₁, tⁱ₂, ..., tⁱ_m] the vector of time points when the *i*th subject has been observed,

• and we have
$$\mathbf{y}_i = [y_i(t_1), y_i(t_2), ..., y_i(t_m)].$$

-Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

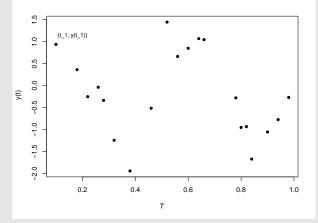

Figure: Sample from a functional data.

-Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

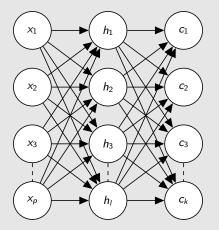

Figure: A 1-hidden layer NN to predict coefficients.

-Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

- We want to train the model using the data y_i,
- but we have a NN that outputs $\hat{\mathbf{c}}$: NN(\mathbf{x}_i) = $\hat{\mathbf{c}}^i$.
- However, we can construct a predicted response $\hat{y}_i(t) = \sum_{k=1}^{K} \hat{c}_k^i B_k(t).$

Functional Output Layer

Functional Output Layer

- We can evaluate $\hat{y}_i(t)$ at \mathbf{t}^i : $\hat{y}_i(\mathbf{t}^i) = [\hat{y}_i(t_1^i), \hat{y}_i(t_2^i), ... \hat{y}_i(t_m^i)]$ = $[\sum_{k=1}^{K} \hat{c}_k^i B_k(t_1^i), \sum_{k=1}^{K} \hat{c}_k^i B_k(t_2^i), ..., \sum_{k=1}^{K} \hat{c}_k^i B_k(t_m^i)]$
- We propose to construct $\mathbf{B}_{K \times m}$ where $B_{k,j} = B_k(t_j)$.
- ▶ Thus $\hat{y}_i(\mathbf{t}^i) = \widehat{\mathbf{c}}_{1 \times K}^i \times \mathbf{B}_{K \times m}$.
- ► That way we can train the model using the following objective function : $L_Y = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1}^{m} [y_i(t_j) \hat{y}_i(t_j)]^2$

How can you train the model with \hat{y} ? It is not the output of the NN!

Functional Output Layer

Functional Output Layer

We can use custom operations that are not part of typical NN model, such as the matrix multiplication $\widehat{\mathbf{c}}_{1\times K}^{i} \times \mathbf{B}_{K\times m}$ because this operation is differentiable.

We only need to use the pytorch or keras *matmult* operator in this case.

Designing neural network layers for functional data analysis \square Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

- By doing this 2-layers process we smooth the response and regress the coefficients onto x jointly. (a single optimization problem)
- We can train the model using the response variable collected
 y_i

•
$$L_Y = \frac{1}{n} \sum_{i=1}^{n} \sum_{j=1}^{m} [y_i(t_j) - \hat{y}_i(t_j)]^2$$

This can be thought of as adding a deterministic layer after the coefficient layer.

Designing neural network layers for functional data analysis \square Neural network architectures for functional data analysis

Functional Output Layer

Functional Output Layer

- ► This creates a continuous and smooth prediction (ŷ(t) exists for every t ∈ [0, T]/interpolates)
- No need to first smooth the data.
- Learning a basis representation of the functional data is beneficial to further address common FDA concerns:
- Irregularly spaced data and smoothness regularization (coherent with literature).

-Neural network architectures for functional data analysis

Functional Input Layer

Functional Input Layer

To process functional input we need to learn a functional weight/parameter β(t).

•
$$y = \beta_0 + \int_T x(t)\beta(t)dt + \varepsilon$$

Our concept is similar to the functional output layer.

Functional Input Layer

Functional Input Layer

• Elements of the first hidden layer are of the form: $h_l = g(\int_T x(t)\beta_l(t))$

• with
$$\beta_l(t) = \sum_{k=1}^{K} c_{l,k} B_l(t)$$

- This means the coefficients c are the parameters we are trying to learn in this layer through back-propagation (learning the functional weight).
- As long as all the operation involving c are differentiable, we should be able to train such model.

-Neural network architectures for functional data analysis

Functional Input Layer

Functional Input Layer

$$h_l = g(\int_T x(t)\beta_l(t)) \tag{1}$$

$$=g(\int_{T}x(t)\sum_{k=1}^{K}c_{l,k}B_{k}(t))$$
(2)

$$=g(\sum_{k=1}^{K}c_{l,k}\int_{T}x(t)B_{k}(t))$$
(3)

$$=g(\sum_{k=1}^{K}c_{l,k}f_{k})$$
(4)

where $f_k = \int_T x(t)B_k(t)$. We can learn *c*, by constructing a simple fully connected layer mapping **f** to **h**:

-Neural network architectures for functional data analysis

-Functional Input Layer

Functional Input Layer

$$f_k = \int_T x(t) B_k(t).$$

- x(t) is not observed as a function, but as a collection of points over [0, T].
- We propose $f_k = \sum_{j=1}^m w_j x(t_j) B_k(t_j)$ (numerical approximation).
- We can perceive this first step as a deterministic layer since f is a just a linear combination of x(t)

Designing neural network layers for functional data analysis
Proposed models and results

Proposed models and results

Function on scalar regression

- We implemented FoS models for simple regression problems.
- Its strength lies in the ability of neural networks to capture non-linear relations.
- We tested our model on multiple simulated data sets and a real data set.
- Wu, S., Beaulac, C. and Cao, J. Neural Networks for Scalar Input and Functional Output, Statistics and Computing, (33), 118, 2023.

- To enforce non-linearity between scalar predictors x and functional response y(t), we made the relation between x and basis coefficients of y(t) non-linear.
- We are able to retrieve the polynomial relation with our proposed model:

Functional neural networks: applications

- Predicting the hourly sugar level of a diabetic over a day given covariates.
- Using the hourly sugar level of a patient over a day to predict the evolution of weight over a year.

- Using brain scan images processed with CNN to predict functional brain data such as EEG.
- All we need is data, the right data and lots of data.

Conclusion

- We designed layers to input or output functional data in modern neural network architectures.
- It allows any form of functional data to be now part of larger multi-modality deep learning models.
- It respects the assumptions of functional data.

- It adds a layer of complexity and hyper parameters to adjusts.
- The implementations are not user-friendly.

I would love to answer your questions.
